Citation: Tam KM, Lai IF. Peripheral corneal ulcer secondary to acquired eyelash trichomegaly following treatment with erlotinib in Asia: a case report. Int J Ophthalmol 2023;16(3):468-469

Dear Editor,

Erlotinib is an epidermal growth factor receptor (EGFR) inhibitor used in the treatment of non-small cell lung cancer. Common side effects of erlotinib include rash and diarrhea, while eyelash trichomegaly and hair disorder are rarely reported, and corneal ulcer is less than 0.1%[1]. To our best knowledge, this is the first such case so far. The patient developed metastasis during the treatment with erlotinib in pulmonary carcinoma. The clinical manifestations were peripheral corneal ulcer and eyelash trichomegaly. The patient successfully underwent epilation, bandage contact lens, topical steroid and lubrication therapy. Subsequently, the patient developed herpes simplex virus epithelial keratitis and acute anterior uveitis (AAU).

This case report was approved by Kiang Wu Hospital. Written informed consent to participate and publication was obtained from the patient. The study was conducted in accordance with the principles of the Declaration of Helsinki.

CASE REPORT

A 52-year-old female have received the treatment with Erlotinib due to the bone metastasis originated from pulmonary carcinoma for about half a year, presenting with eyelash trichomegaly (Figure 1A). She complained of mild foreign body sensation without redness, pain, photophobia and ocular discharge in her right eye. No history of eye disease, contact lens use or autoimmune disease. Slit-lamp examination showed mild conjunctival injection. Peripheral corneal ulcer occurred on the cornea at around 11 o’clock, and was separated from it at lucid interval in the right eye (Figure 1B). Her intensely matted clumped eyelashes would contact to the corneal ulcer. Blood investigations revealed white blood cell count: $3.17 \times 10^9$/L and hemoglobin: 106 g/L. Urine, liver and kidney function were normal. Herpes simplex virus immunoglobulin M, C-reactive protein, and erythrocyte sedimentation rate were normal with normal chest radiography. Initially, the patient was given topical antibiotics and lubrication with epilation for about 5d. However, her condition failed to respond to the treatment, the corneal ulcer expanded (Figure 1C). After stopped application of antibiotic, with the addition of topical steroid, the lesion gradually shrank, but the healing process remained slow. During the follow-up, the deciduous eyelashes were found adhered to the corneal ulcer, affecting the healing of the lesion (Figure 1D). Finally, the patient successfully underwent epilation, bandage contact lens, topical steroid and lubrication treatment without discontinuing erlotinib (Figure 1E, 1F). However, 3wk after the recovery from corneal ulcer, the patient developed dendritic epithelial ulcer and AAU.

The dendritic epithelial ulcer was located in the center of the cornea, AAU was accompanied with granulomatous and small keratic precipitates (Figure 2B), and mild inflammation occurred in the anterior chamber. After oral and topical antiviral drugs, dendrite keratopathy (Figure 2A) reduced and recovered. AAU improved after 2mo of topical steroid treatment.

DISCUSSION

Erlotinib is a tyrosine kinase inhibitor of EGFR. EGFR is widely expressed on the ocular surface and periocular adnexa. Systemic administration of EGFR inhibitors may therefore lead to adverse reactions to ocular epithelial tissue regeneration and periocular adnexa. Clinically reported ocular adverse reactions of erlotinib include eyelash trichomegaly[2], blepharitis, corneal epithelial defect[1], infectious corneal ulcer[1,4], and even corneal perforation[9]. Symptoms of eyelash trichomegaly include curly, irregular, excessively long and brittle eyelashes. In our case, the factors of corneal ulcer...
formation were considered as follows: A: Erlotinib inhibited corneal epithelial regeneration and healing; B: Matted clumped eyelashes in contact with cornea can cause mechanical injury. Interestingly, brittle eyelash will adhere to corneal lesions and interfere with the healing of corneal ulcer. In this case, despite of epilation, antibiotics and artificial tears, the lesion of the patient remained enlarged, but she was then cured through epilation, bandage contact lens, topical steroid and artificial tears without discontinuing erlotinib. Although discontinuing erlotinib and topical medicine have been reported to be capable of curing keratopathy in several literatures\cite{1,5}, the progression of the primary disease may be prompted instead. Erlotinib is not considered to be the cause of advanced herpes simplex virus epithelial keratitis and AAU. Probably, the compromised immune system of carcinoma patient may lead to the underlying viral attack. Consequently, the significance of the potential peripheral corneal ulcer in patients treated with erlotinib should be highlighted in ophthalmologists. In addition, bandage contact lens and topical steroid may be conducive to the healing of such corneal ulcer, despite the continuous administration of erlotinib.
